Inschrijving en accreditatie

Inschrijven voor deze wetenschappelijke voorjaarsvergadering kan via het aanmeldformulier op de website.

Deze wetenschappelijke voorjaarsvergadering wordt geaccrediteerd en gewaardeerd met 8 accreditatiepunten door de NVT. Accreditatie is verder aangevraagd bij de NAPA en het Verpleegkundig specialisten register. De behaalde accreditatiepunten worden automatisch bijgeschreven in het persoonlijk GAIA dossier.

Algemene Ledenvergadering

Toegang tot de algemene ledenvergadering hebben alle gewone leden van de vereniging, alle bestuursleden, alle ereleden, alle senior leden alsmede de voorzitter en secretaris van de Juniorkamer.

SEX-RELATED DIFFERENCES IN OUTCOMES OF SINGLE- AND MULTI-ARTERIAL CORONARY ARTERY BYPASS GRAFTING: INSIGHTS FROM THE NETHERLANDS HEART REGISTRATION

Sophie H.Q. Beukers¹, Edgar J. Daeter¹, Lineke Derks², Geoffrey T.L. Kloppenburg¹ on behalf of the participating centres of the Cardiothoracic Surgery Registration Committee of the Netherlands Heart Registration

¹*Department of cardiothoracic surgery, St. Antonius Hospital, Nieuwegein, The Netherlands*

²*Netherlands Heart Registration, Utrecht, The Netherlands*

Objectives

Women are known to suffer from increased mortality and major adverse cardiac events rates (MACCEs) after coronary artery bypass grafting (CABG) compared to men. This study evaluates the effect of sex on revascularization strategies, meaning use of single or multiple arterial grafts (SAG or MAG), and outcomes after CABG.

Methods

Data were gathered retrospectively from the Netherlands Heart Registration database. Patients undergoing isolated CABG were divided into groups treated with SAG or MAG. Using risk adjusted cox proportional hazard regression analysis, the effect of sex on the revascularization strategy and postoperative outcomes was assessed. Secondary analysis was conducted on a subset of patients aged 70 years or younger at baseline.

Results

The study included 51137 patients, of which 19.1% was female. When compared to men, women were older, suffered from more comorbidity in both subgroups and received fewer arterial grafts. Women were more prone to MACCEs (11.2% vs 14.3%, $p < 0.001$) and showed inferior survival rates. While use of MAG led to a lower repeat revascularization rate in men ($p = 0.022$), this was not the case in women. Cox regression analysis did not independently associate the female sex with inferior survival. In a younger population, a survival benefit was observed after revascularization with MAG, to the point where survival did not differ between sexes. MAG was associated with a 25% mortality reduction.

Conclusion

Women receive fewer arterial grafts and anastomoses as opposed to men. In a younger patient population, the survival difference between sexes disappears when patients are treated with MAG.

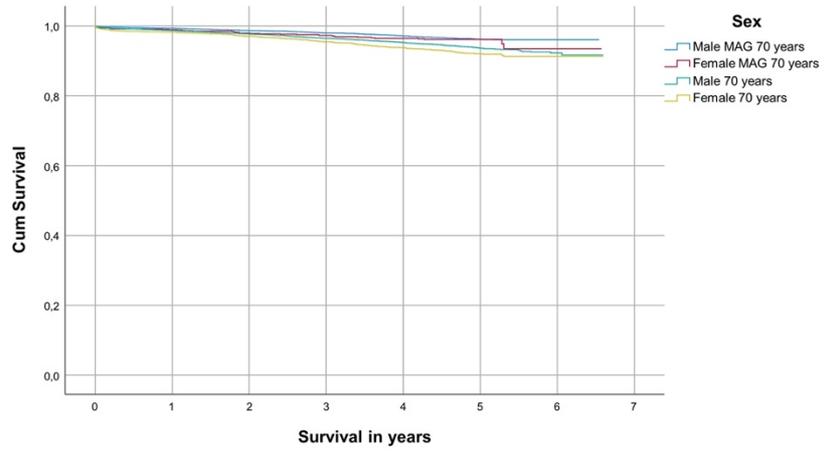

Figure 1. Kaplan Meier curve for survival in years of men and women aged 70 years and younger, for both the entire population and after multiple arterial grafting (MAG).

Objectives

Investigate the biocompatibility of a novel lung sealant (gelatin patch impregnated with functionalized polyoxazolines, NHS-POx), in terms of inflammation, wound healing and biodegradation.

Methods

Three lesions are made on the right lung of adult female sheep. Study groups (NHS-POx, fibrin patch [TachoSil®] and untreated control) were randomly allocated. Blinded histological assessment was performed at 5, 14 and 42 days (n=4 animals/term), using semi-quantitative scales (0-4) based on immune cells (polymorphonuclear cells, lymphocytes, plasma cells, macrophages, giant cells, necrosis) and biomaterial response (fibrosis, neovascularization, fatty infiltrate). Because a labeling mistake was suspected, original and adapted datasets were obtained (6 weeks) for post-hoc analysis.

Results

NHS-POx had significantly elevated immune response scores at five days compared to control (11.5 vs 7, p=0.005), as did the fibrin patch at two weeks (14 vs 7, p=0.022). By six weeks, cell response equalized among groups (p=0.22). However, one case of granulomatous inflammation to residual patch was noted in both a fibrin patch and a probable fibrin patch (labeling error). Healing, fibrosis and neovascularization were consistent across groups, showing localized pleural thickening. The NHS-POx patch displayed mesothelial coverage after two weeks, and full degradation both macro- and microscopically at six weeks, with the patch material substituted by extracellular matrix (adapted data).

Conclusion

The biocompatibility profile of NHS-POx seems comparable to favorable compared to the clinically frequently used fibrin patch. Rapid biodegradation and absent chronic inflammation or foreign body reaction may improve tissue regeneration, indicating promise for clinical use.

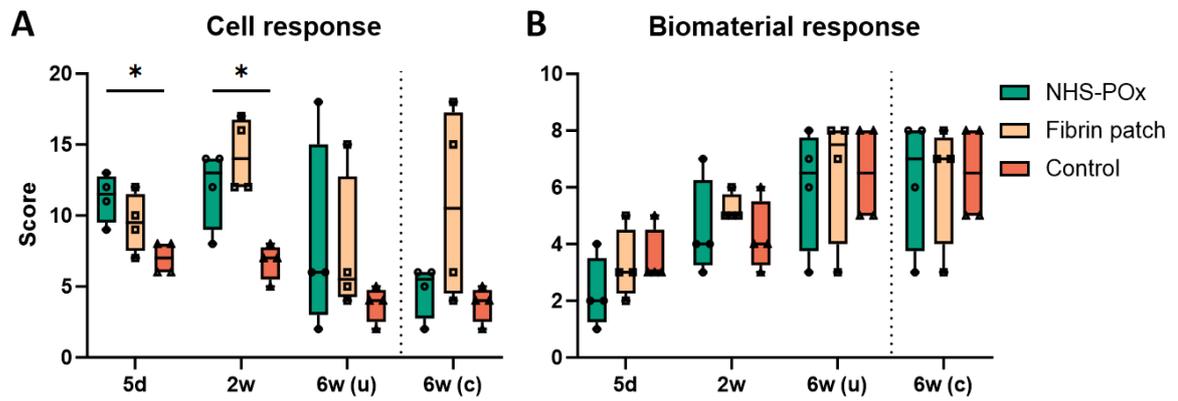

Figure 2A) Total cell response score (sum of semiquantitative scores [0-4] on polymorphonuclear cells, lymphocytes, plasma cells, macrophages, giant cells, necrosis, max 24 points). **B)** Total biomaterial response score (sum of semiquantitative scores [0-4] on neovascularization, fibrosis, fatty infiltrate, max 12 points).

² Department of Cardiology, University Medical Center Groningen

³ Department of Cardiology, Erasmus Medical Center Rotterdam

⁴ Department of Cardiothoracic Surgery, University Medical Center Utrecht

Objectives

Heart transplantations (HTx) have been performed with hearts donated after circulatory death (DCD) in the Netherlands since 2021. Most of these DCD donors decess after switch off of life support, and are categorized as DCD-III donors which is internationally considered the "standard" DCD donor. However, the Dutch donor pool consists of an additional pool: donation after euthanasia (DCD-V). Here, we compare DCD-III and DCD-V HTx.

Methods

The data of DCD HTx performed at the UMCG in the period 1/3/2021–1/3/2024 were retrospectively collected. The DCD population was subdivided in the DCD-III and DCD-V cases. Both donor and recipient characteristics and postoperative outcome were compared.

Results

Eighteen DCD HTx were performed, of which 6 (33%) were DCD-V HTx. More female donors were present in the DCD-V population (83%, versus 25% in DCD-III, $p=0.043$). Ischemic times and preservation times were comparable. No significant differences were found in recipient characteristics. Numerically, the need for postoperative extracorporeal life support (ECLS) in DCD-III (5 cases, 42%) versus 0% in DCD-V ($p=0.114$) was striking. Postoperative left ventricular function was comparable. Survival between both groups (91,7% in DCD-III versus 100% in DCD-V) was similar ($p=0.564$).

Conclusion

We compared HTx following DCD-III versus DCD-V in a single center. Most importantly, DCD-V is a non-inferior part of the Dutch donor pool and offers a substantial number of additional heart transplantations. The postoperative need of ECLS should be studied more in depth in a bigger cohort. Future studies will incorporate an overview of the full Dutch landscape.

10.00 – 10.30 uur

THORACOSCOPIC-ASSISTED, MINIMALLY INVASIVE VERSUS CONVENTIONAL, OFF-PUMP BYPASS GRAFTING FOR SINGLE VESSEL CORONARY ARTERY DISEASE – A PROPENSITY SCORE MATCHED ANALYSIS

Objective

This study compared perioperative outcomes after off-pump revascularization through a thoracoscopic-assisted (non-robotic) minimally invasive approach (Endo-CAB) or sternotomy approach (OPCAB) for patients with single vessel left anterior descending (LAD) disease.

Methods

In this retrospective, propensity matched cohort study, 266 consecutive patients were included in the Endo-CAB group (n=136) and OPCAB group (n=130). After propensity score matching 116 Endo-CAB and 116 OPCAB patients were compared. 'Textbook outcome' was defined as the absence of 30-day mortality, re-exploration for bleeding, postoperative ischemia, cardiac tamponade, cerebrovascular events, wound infection, new-onset arrhythmias, pneumonia, placement of chest drains and prolonged hospital stay (> 7 days). Multivariable regression analysis was performed to identify independent predictors for textbook outcome.

Results

Textbook outcome occurred significantly more frequent in the Endo-CAB group compared to the OPCAB group (81.9% vs. 59.5%, $p < 0.001$). Patients undergoing Endo-CAB surgery had shorter hospital admission (3.0 [3.0 – 4.0] vs. 5.0 [4.0 – 6.0] days, $p < 0.001$), less blood loss (225 [150 – 355] vs. 450 [350 – 600] ml, $p < 0.001$). Other perioperative outcomes were comparable for both groups. Regression analysis demonstrated that Endo-CAB approach was an independent positive predictor for textbook outcome (OR 3.02, 95% CI 1.61-5.66, $p < 0.001$).

Conclusions

Our study suggests that patients undergoing Endo-CAB surgery have improved perioperative outcome resulting in higher rates of textbook outcome for the treatment of single vessel CAD. This technique could be widely available since routine thoracoscopic instruments are used.

Endo-CAB vs. OPCAB 30-day outcome

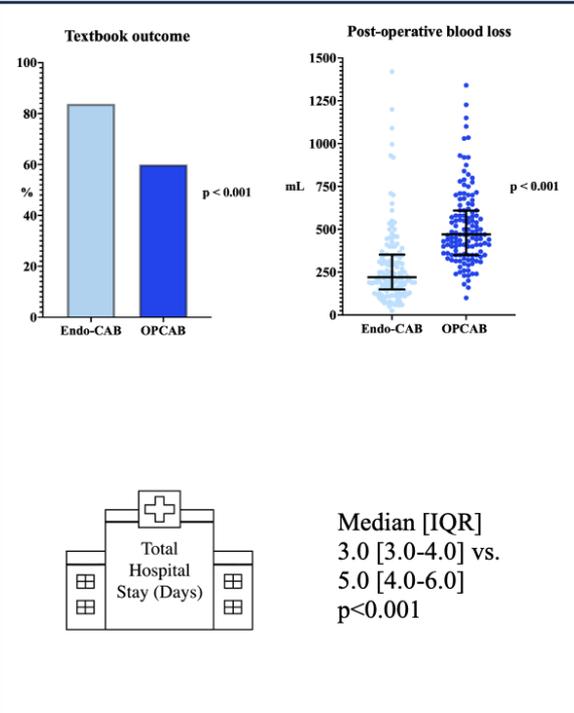

Summary

Background: This study compared perioperative outcomes of a thorascopic-assisted (non-robotic) minimally invasive approach (Endo-CAB) or sternotomy approach (OPCAB) for single vessel LAD disease.

Methods: Retrospective propensity matched cohort study including 132 patients after matching (116 Endo-CAB, 116 OPCAB). The primary objective was comparison of Textbook outcome, defined as the absence of 30-day mortality, re-exploration for bleeding, postoperative ischemia, cardiac tamponade, cerebrovascular events, wound infection, new-onset arrhythmias, pneumonia, placement of chest drains and prolonged hospital stay (>7 days).

Results: Textbook outcome occurred significantly more frequent in the Endo-CAB group compared to the OPCAB group (81.9% vs. 59.5%, $p < 0.001$). Patients undergoing Endo-CAB surgery had shorter hospital admission (3.0 [3.0 – 4.0] vs. 5.0 [4.0 – 6.0] days, $p < 0.001$), less blood loss (225 [150 – 355] vs. 450 [350 – 600] ml, $p < 0.001$).

Conclusion: Patients undergoing Endo-CAB surgery have improved perioperative outcome resulting in higher rates of textbook outcome for the treatment of single vessel CAD.

INCIDENCE AND PROGRESSION OF PERICARDIAL EFFUSION AFTER CARDIAC SURGERY ON ROUTINE ECHOCARDIOGRAPHY: A SYSTEMATIC REVIEW

S.R. van Dinter¹, L.W. Wollersheim², H. Dieker³, R.H. Heijmen¹, W.W.L. Li¹, A.F.T.M. Verhagen¹

¹ *Department of Cardiothoracic Surgery, Radboudumc, Nijmegen, The Netherlands*

² *Department of Cardiothoracic Surgery, Medical Center Leeuwarden, Leeuwarden, The Netherlands*

³ *Department of Cardiology, Radboudumc, Nijmegen, The Netherlands*

Objectives

Postoperative pericardial effusion (PPE) after cardiac surgery occurs frequently. Reported incidence varies widely between 5-85%. Although often inconsequential, PPE can evolve into life-threatening cardiac tamponade (CT) requiring urgent reintervention. However, probability and risk factors of PPE leading to CT remain unclear. In this review, we summarized published data on incidence of PPE after cardiac surgery, its development into CT and the rate of reinterventions.

Methods

We performed a systematic search on PubMed, Embase and Web Of Science. Articles describing PPE after cardiac surgery with at least one routine echocardiogram were included.

Results

Twenty-six of 2693 articles were included, combining 8497 patients. Incidence of PPE was 47.7%, and in 1.6% PPE-related reinterventions were performed. Reinterventions were most frequent after aortic surgery (6.0%), and significantly less after valve (3.3%) and CABG surgery (1.2%, $p < 0.001$). In 4083 patients size specification of PPE was documented. Large PPE (>14mm circumferential or >19mm loculated effusion) led to reintervention in 54.3% of cases, compared to 2.0% and 2.4% for small and moderate effusion (figure 1C). Of all reported reinterventions, 60% had symptomatology of CT, while 13% were performed in asymptomatic patients (of which 75% had large effusion). In 27% symptomatology was not reported.

Conclusions

PPE-related reinterventions are rare, but more common after aortic surgery and/or with large effusion. A considerable number of reinterventions were performed in asymptomatic patients or with unreported symptomatology, whereas half of large effusions were treated conservatively. Further research with routine echocardiography after cardiac surgery and elaborate description of symptomatology is warranted.

Figure 1 – The total incidence of PPE and reinterventions, the symptomatology in patients with reinterventions, and the rate of reintervention per effusion size

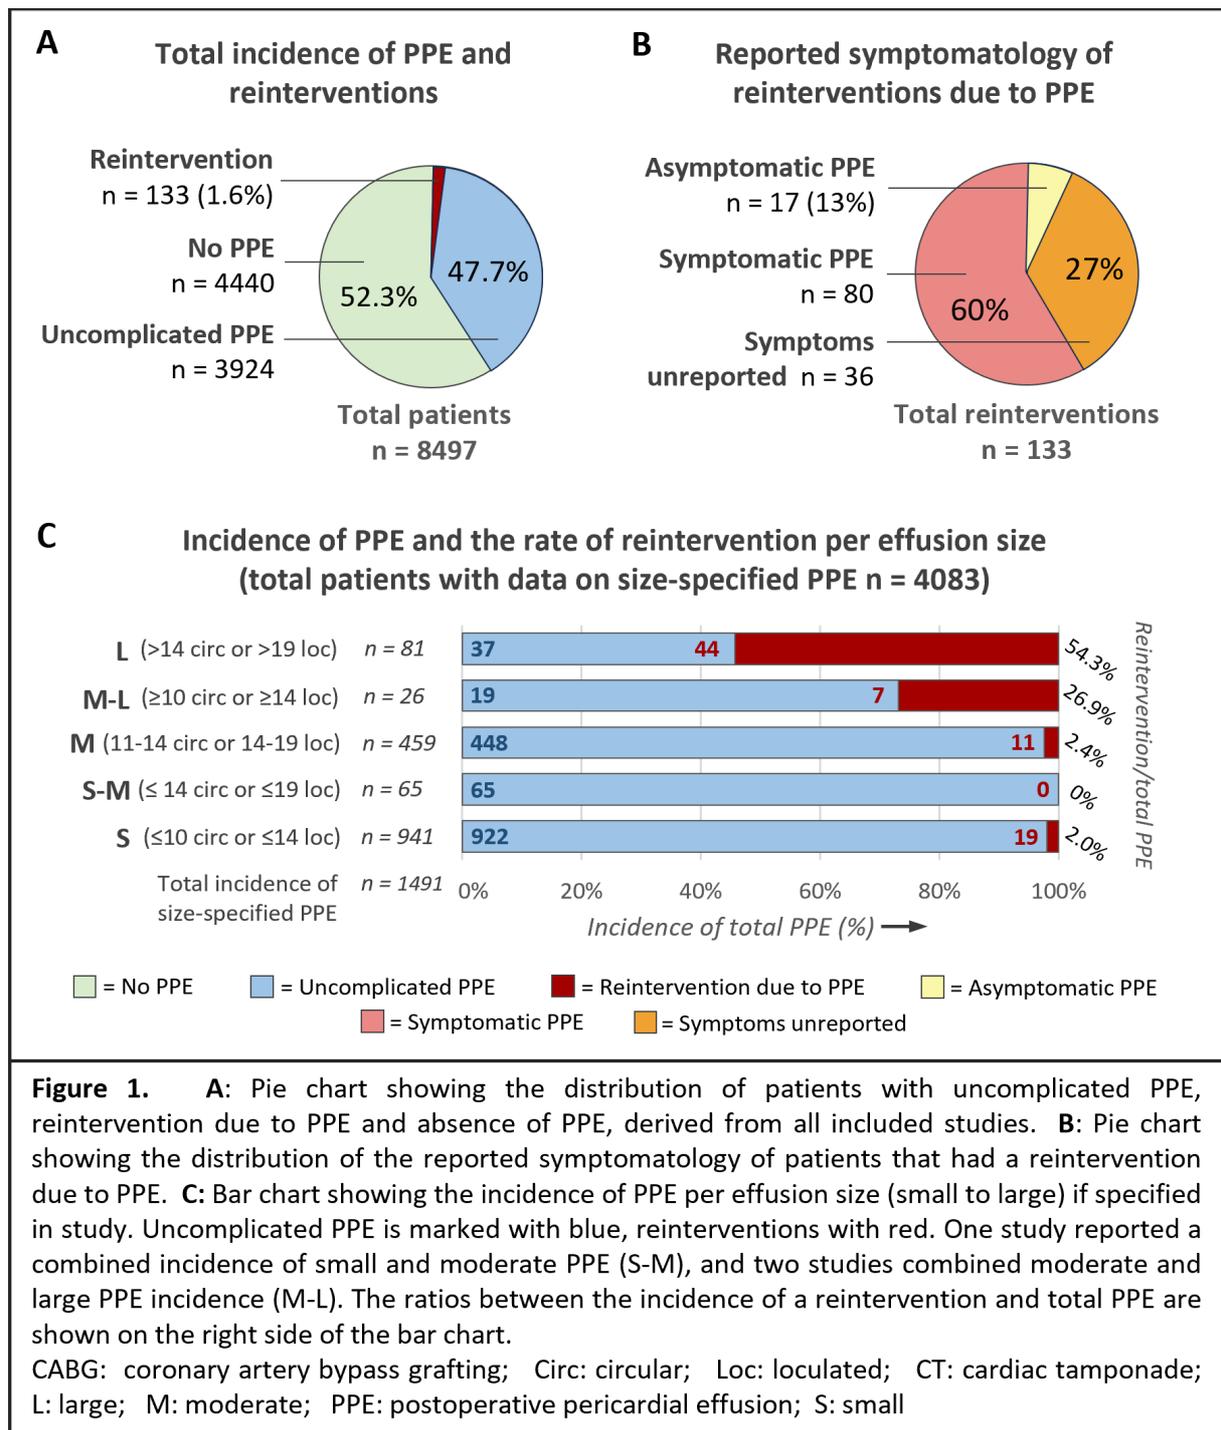

Figure 1. **A:** Pie chart showing the distribution of patients with uncomplicated PPE, reintervention due to PPE and absence of PPE, derived from all included studies. **B:** Pie chart showing the distribution of the reported symptomatology of patients that had a reintervention due to PPE. **C:** Bar chart showing the incidence of PPE per effusion size (small to large) if specified in study. Uncomplicated PPE is marked with blue, reinterventions with red. One study reported a combined incidence of small and moderate PPE (S-M), and two studies combined moderate and large PPE incidence (M-L). The ratios between the incidence of a reintervention and total PPE are shown on the right side of the bar chart.

³ Department of Clinical Epidemiology, Leiden University Medical Center, Leiden;

⁴ Department of Biomedical Data Science, Leiden University Medical Center, Leiden

Objective

Literature presents conflicting results on the pros and cons of pledget-reinforced sutures during surgical aortic valve replacement (SAVR). We aimed to investigate the effect of pledget-reinforced sutures versus sutures without pledgets during SAVR on different outcomes in a systematic review and meta-analysis.

Methods

A literature search was performed in PubMed, Cochrane and Embase databases. Studies must include patients undergoing SAVR and must compare any pledget-reinforced with any suturing technique without pledgets. The primary outcome was paravalvular leakage (PVL), and secondary outcomes comprised thromboembolism, endocarditis, mortality, mean pressure gradient (MPG) and effective orifice area (EOA). Results were pooled using a random-effects model as risk ratios (RRs) or mean differences (MDs) for which the no pledgets group served as reference.

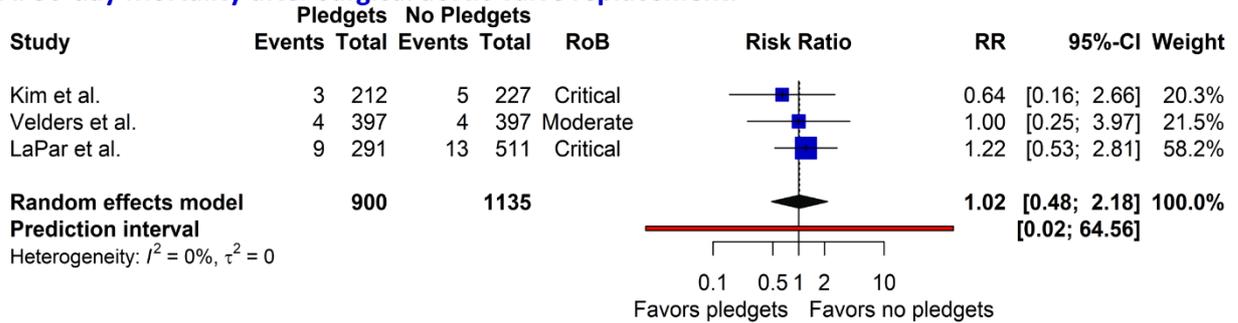

Results

Eight studies, all observational, met the inclusion criteria. The risk of bias was critical in six studies, and high and moderate in the other two. The pooled RR for moderate or greater PVL was 0.76 (95% confidence interval [CI] 0.14, 4.09). The pooled RR for mortality at 30-days was 1.02 (95% CI 0.54, 1.94). For MPG and EOA at 1-year follow-up, the pooled MDs were 0.60 mmHg (95% CI -4.92, 6.11) and -0.03 cm² (95% CI -0.18, 0.12), respectively.

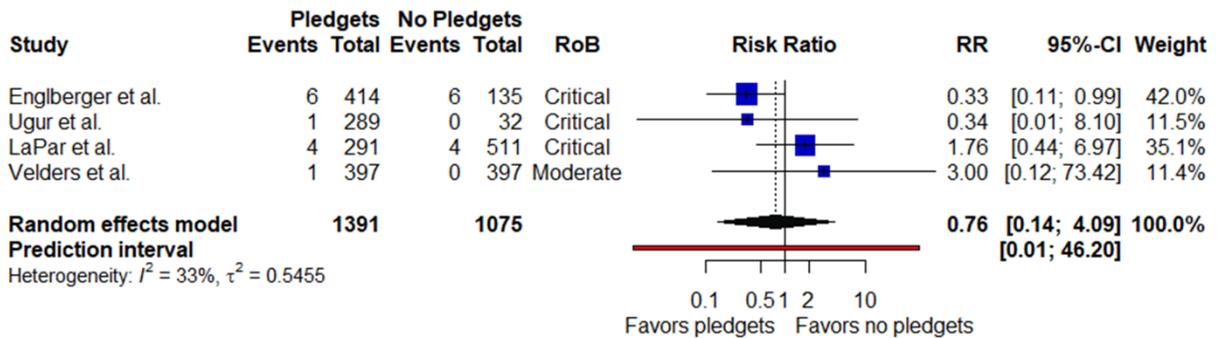

Conclusions

Literature on the use of pledget-reinforced sutures during SAVR is at high risk of bias. Pooled results are inconclusive regarding superiority of either pledget-reinforced sutures or sutures without pledgets. to support or oppose the use of pledget-reinforced sutures.

Objective

New echocardiographic definitions have been proposed for hemodynamic structural valve deterioration (SVD), mainly based on worsened hemodynamics as compared to the discharge echo (*Figure 1*). We aimed to study their consistency in classifying SVD after surgical aortic valve replacement (SAVR).

Methods

Data were used of SAVR patients implanted in a multicenter, prospective cohort study with 5-year follow-up. Serial echocardiographic parameters were assessed by an independent core laboratory. Moderate or greater stenotic hemodynamic SVD was defined according to Capodanno *et al.*, Dvir *et al.*, and the Valve Academic Research Consortium (VARC) 3; regurgitation data was not considered in this analysis. Their consistency was evaluated by calculating how many patients that were classified with SVD at one timepoint were also classified with SVD at the subsequent timepoint.

Results

A total of 1118 patients were implanted. The mean age was 70 years and 75% were male. Hemodynamic SVD at any visit was present in 51 (4.6%), 32 (2.9%), and 34 (3.0%) patients according to Capodanno, Dvir, and VARC-3. 1064 (95%) patients were never labelled with SVD by any definition. After the first classification with SVD, 59%, 59%, and 65% had no subsequent SVD classification according to Capodanno, Dvir, and VARC-3, respectively.

Conclusions

The current definitions of hemodynamic SVD are inconsistent discriminators for the detection of stenotic hemodynamic SVD. While the diagnosis of SVD may be categorical, echocardiographic indices lack this degree of precision in the first 5-years after SAVR. The observed inconsistencies challenges the clinical usefulness of these definitions.

Figure 1. Contemporary definitions of moderate or greater stenotic hemodynamic structural valve deterioration after aortic valve replacement.

ATRIAL ELECTROPHYSIOLOGICAL PROPERTIES OF NORMOTHERMIC-PERFUSED HEARTS DONATED AFTER CIRCULATORY DEATH

Mark F.A. Bierhuizen; Hongxian Xiang; Mathijs van Schie; Jorik H. Amesz; Sanne J.J. Langmuur; Paul Knops; Olivier C. Manintveld; Jolanda Kluin; Yannick J.H.J. Taverne; Natasja M.S. de Groot

Erasmus Medical Center, Rotterdam

Objectives

Donation after circulatory death (DCD) hearts undergo a period of ischemia during transplantation. Atrial ischemia is considered an important contributor to the development of atrial electrophysiological abnormalities. The objective was to characterize atrial electrophysiological properties of DCD hearts during ex-situ heart perfusion (ESHP).

Methods

High-resolution epicardial mapping was performed in 10 human DCD hearts during ESHP and compared to 10 control patients undergoing intra-operative mapping during bypass surgery. Unipolar potential voltages, fractionation, conduction velocity (CV) and conduction block (CB) were quantified in the right atrium (RA) and left atrium (LA). The occurrence of post-transplantation atrial fibrillation (AF), flutter (AFL) and sinus node dysfunction (SND) were evaluated.

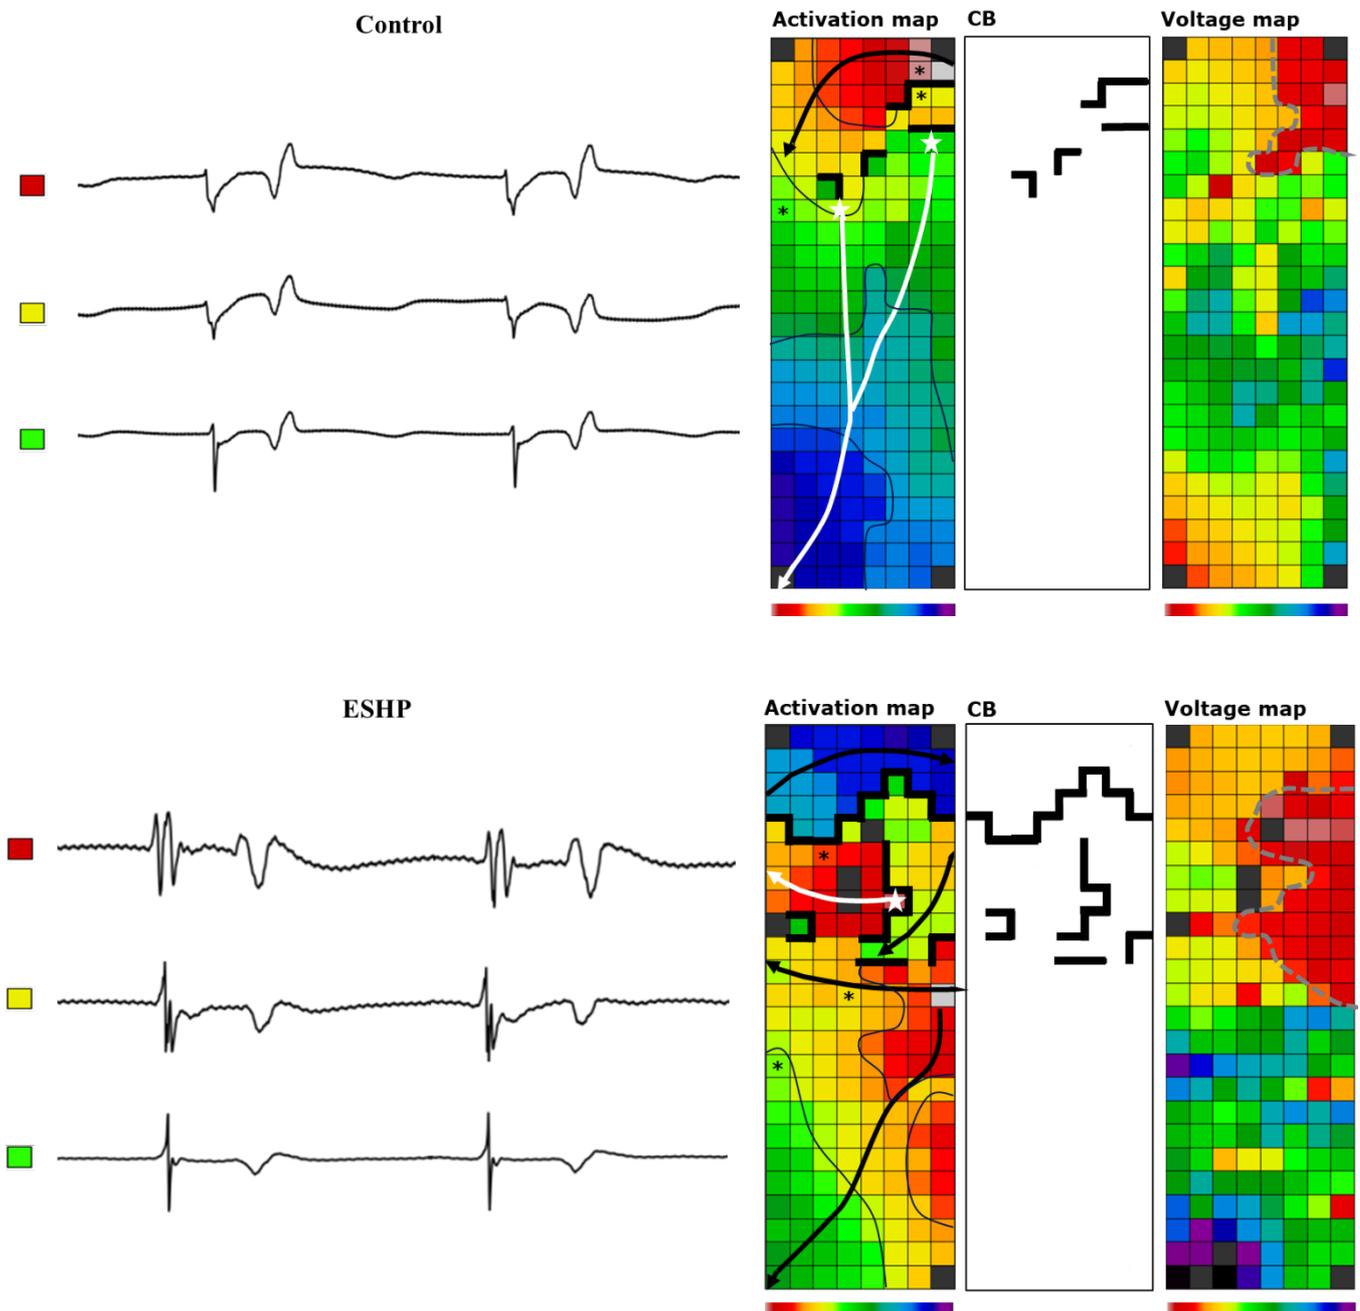

Results

In DCD hearts, unipolar potential voltages (2.8[2.4 – 3.0] vs. 5.3[3.9 – 6.1] mV, $p=0.002$) and CV (74.2[71.4 – 78.8] vs. 91.7[89.2 – 96.3] m/s, $p<0.001$) were lower at the RA compared to the control group. A larger proportion of CB was observed in the RA (8.4[5.1 – 10.5] vs. 2.4[1.0 – 3.2] %, $p=0.002$) and LA (7.9[5.3 – 11.3] vs. 0.5[0.1 – 1.1] %, $p<0.001$) of DCD hearts. Single potentials were less frequently recorded in the RA (70.4[57.2 – 77.4] vs. 85.2[80.1 – 89.6] %, $p=0.003$) and LA (50.9[33.8 – 65.7] vs. 80.7[69.5 – 90.7] %, $p=0.011$). Two patients who developed early post-transplantation SND had areas of CB surrounding the SAN (18.1 vs 5.5 %, $p = 0.286$).

Conclusion

During ESHP, the atria of DCD hearts are characterized by abnormal electrical signal morphologies and patterns of activation. Future studies will have to demonstrate that a higher degree of CB is predictive for SND.

Figure 2: Typical epicardial unipolar electrograms of the RA of a patient in the control group and a DCD heart during ESHP, showing more fractionated potentials, more CB and lower voltages. The right panel shows the corresponding activation map, CB and voltage maps of these recordings. * represent the illustrated electrograms in the left panel; Wave-front direction is illustrated by the black and white arrows; Isochronal lines are illustrated by thin black lines and CB by thick black lines; LVAs are highlighted by the grey dotted line. CB: conduction block; LVA: low voltage areas.

Objectives

Deep hypothermic circulatory arrest, antegrade brain perfusion and cardioplegic arrest are commonly used organ protection techniques in aortic arch surgery. However, mortality and morbidity remain high in patients with advanced cardiovascular disease. Here we describe our experience with continuous organ perfusion during aortic arch surgery.

Methods

Cardiopulmonary bypass access was achieved through axillary artery for continuous cerebral perfusion under bilateral TCD and EEG monitoring and femoral cannulation (EndoReturn with a Coda® balloon) for visceral perfusion. Cardiac perfusion was reinitiated with warm blood after root surgery (MYOterm XP®). Systemic cooling was applied between 28-32 degrees.

Results

From June 2022 to February 2024, 20 elective patients underwent aortic arch surgery using continuous organ perfusion (Table 1). Fourteen were operated for chronic Type A or B dissection, and 6 for arch aneurysm. Five were redo procedures. Circulatory arrest was avoided in 12 patients, resulting in maximum perioperative lactate between 1.0-3.0 mmol/L. In the other 8 patients, median arrest time was 35 min [range 7-69], and maximum perioperative lactate ranged between 2.0-5.1mmol/L. Cardioplegic arrest was avoided in 3 patients and limited to a median of 90 minutes [28-168] in those requiring root surgery. Median intensive care stay was 1 day [range 1-9 days], median ventilation time 9 hours [3-150]. One patient had a transient ischemic attack, and all patients survived until hospital discharge after a median of 8 days [range 4-30].

Conclusion

Beating heart aortic arch surgery, while avoiding deep hypothermic circulatory arrest, is feasible, and could allow less mortality and faster recovery.

PERCUTANEOUS CORONARY INTERVENTION WITH DRUG-ELUTING STENTS VERSUS CORONARY BYPASS SURGERY FOR COMPLEX CORONARY ARTERY DISEASE: A BAYESIAN ANALYSIS OF RANDOMIZED TRIALS

Michal J. Kawczynski, MD^{1,2}, Andrea Gabrio, PhD³, Jos G. Maessen, MD, PhD^{1,2}, Arnoud W.J. van 't Hof, MD, PhD^{2,4,5}, James M. Brophy, MD, PhD⁵, Can Gollmann-Tepeköylü, MD, PhD⁷, Peyman Sardari Nia, MD, PhD^{1,2}, Pieter A. Vriesendorp, MD, PhD^{2,4}, and Samuel Heuts, MD, PhD^{1,2,*}

** Presenter; ¹ Department of Cardiothoracic Surgery, Maastricht University Medical Center (MUMC+), Maastricht, the Netherlands; ² Cardiovascular Research Institute Maastricht (CARIM), Maastricht University, Maastricht, the Netherlands; ³ Department of Methodology and Statistics, University Maastricht, Maastricht, the Netherlands; ⁴ Department of Cardiology, Maastricht University Medical Center (MUMC+), Maastricht, the Netherlands; ⁵ Department of Cardiology, Zuyderland Medisch Centrum, Heerlen, the Netherlands; ⁶ McGill University Health Center, Center for Health Outcome Research (CORE), Montreal, Quebec, Canada; ⁷ Department of Cardiac Surgery, Medical University of Innsbruck, Innsbruck, Austria*

Objectives

We aimed to assess the totality of randomized evidence comparing percutaneous coronary interventions with drug-eluting stents (DES-PCI) to coronary artery bypass grafting (CABG) for complex coronary artery disease (CAD), under the Bayesian statistical framework*.

Methods

A Bayesian re-analysis of trials comparing DES-PCI to CABG with 5-year follow-up was performed. The primary outcome was all-cause mortality at five years; secondary outcomes were stroke, myocardial infarction, and repeat revascularization. Endpoints were reported in relative risks (RR) and absolute risk differences (ARD), with 95% credible intervals (CrI). Kaplan-Meier curves were used to reconstruct individual patient data. This study was registered in PROSPERO (CRD42024512897, date: February 25th 2024).

Results

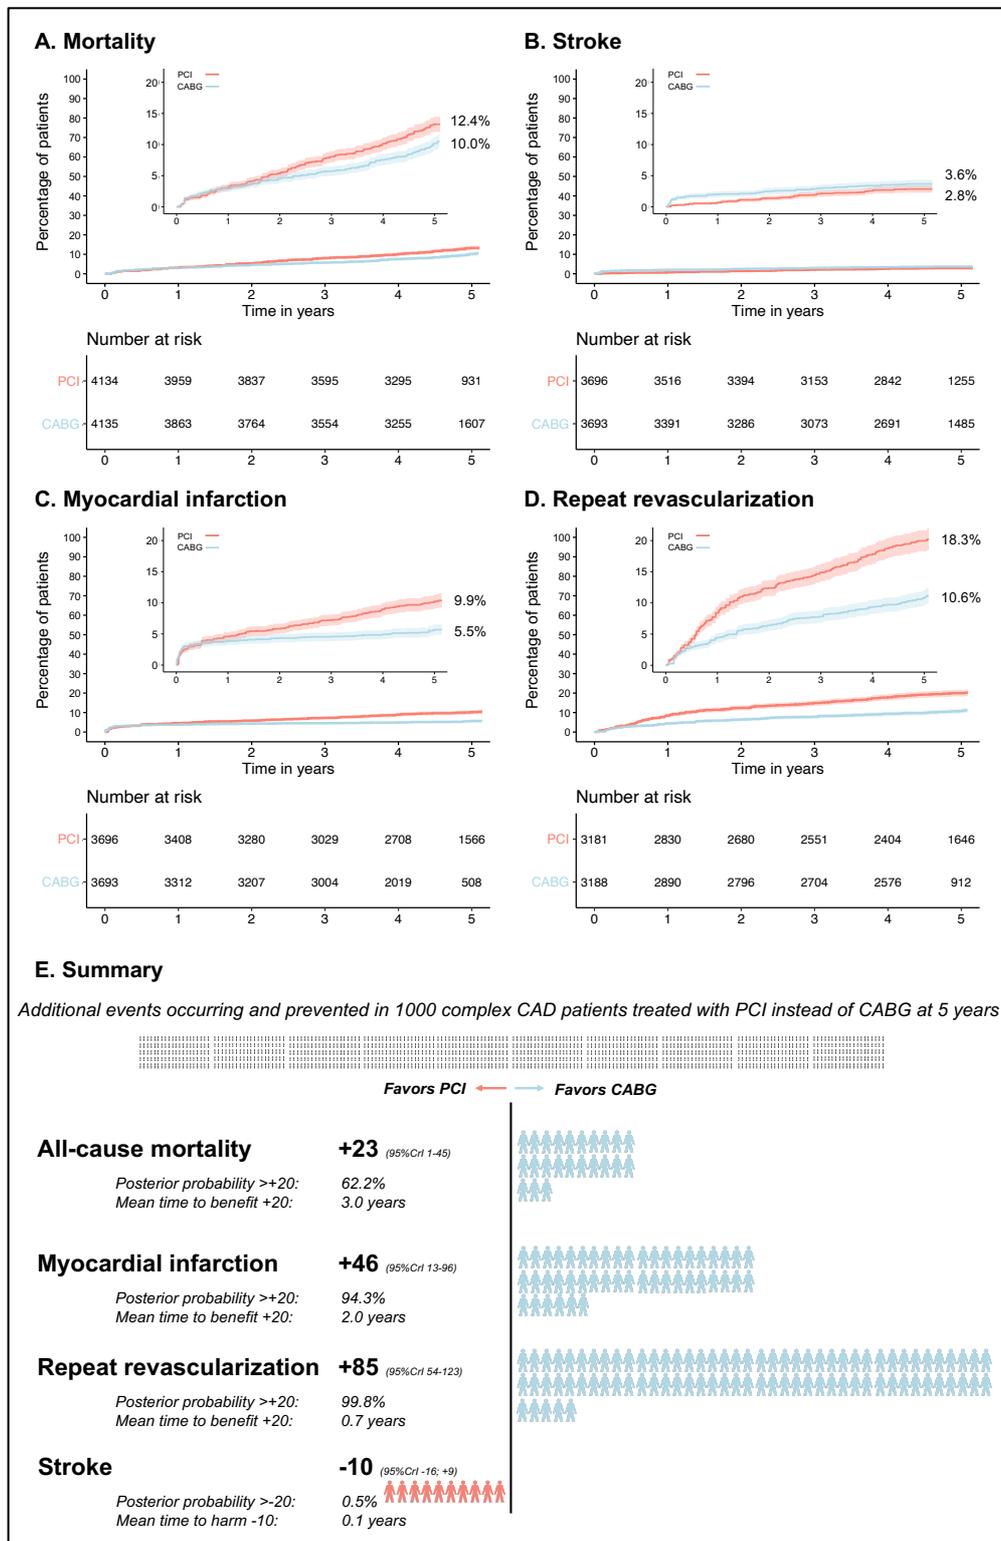

Six studies (SYNTAX, NOBLE, EXCEL, PRECOMBAT, BEST, FREEDOM) comprising 8269 patients (DES-PCI n=4134, CABG n=4135) were re-analyzed using Bayesian statistics. All-cause mortality at 5 years was increased with PCI (median RR 1.23 (95%CrI 1.01-1.45), with a median ARD of +2.3% (95%CrI 0.1-4.5%). For stroke, MI, and repeat revascularization, the median RRs were 0.79 (95%CrI 0.54-1.25), 1.84 (95%CrI 1.23-2.75), and 1.80 (95%CrI 1.51-2.16) for PCI, respectively (**Figure 1A-D**). Illustratively, in a sample of 1000 patients undergoing DES-PCI instead of CABG for complex CAD, a median of 23 additional deaths, 46 myocardial infarctions and 85 repeat revascularizations occurred at five years, while 10 strokes were prevented (**Figure 1E**).

Conclusion

In complex CAD, CABG provides a clinically relevant benefit over DES PCI at five years. These findings offer an intuitive interpretation of revascularization outcomes in complex CAD, and may guide the heart-team and the shared decision-making process.

* When accepted for a potential presentation during the meeting, the concept of Bayesian statistical analysis will be presented to the audience as well, making them more familiar with this innovative statistical concept.

FIGURE 1. Graphical summary of the findings of this Bayesian re-analysis of randomized trials comparing DES-PCI to CABG for complex CAD.

CAD: coronary artery disease, PCI: percutaneous coronary intervention.

Objectives

To describe contemporary survival outcomes after surgery for type-A aortic dissection in The Netherlands.

Methods

All patients who underwent surgery for type-A aortic dissection in The Netherlands between 2018 and 2021 were identified in the Netherlands Heart Registration (NHR). NHR data were linked to data about (cause of) death from Statistics Netherlands. Time trends for in-hospital mortality were analysed, and age- and sex-adjusted mortality odds ratios were compared across years. The occurrence of death over time was graphically illustrated, stratified by cause of death.

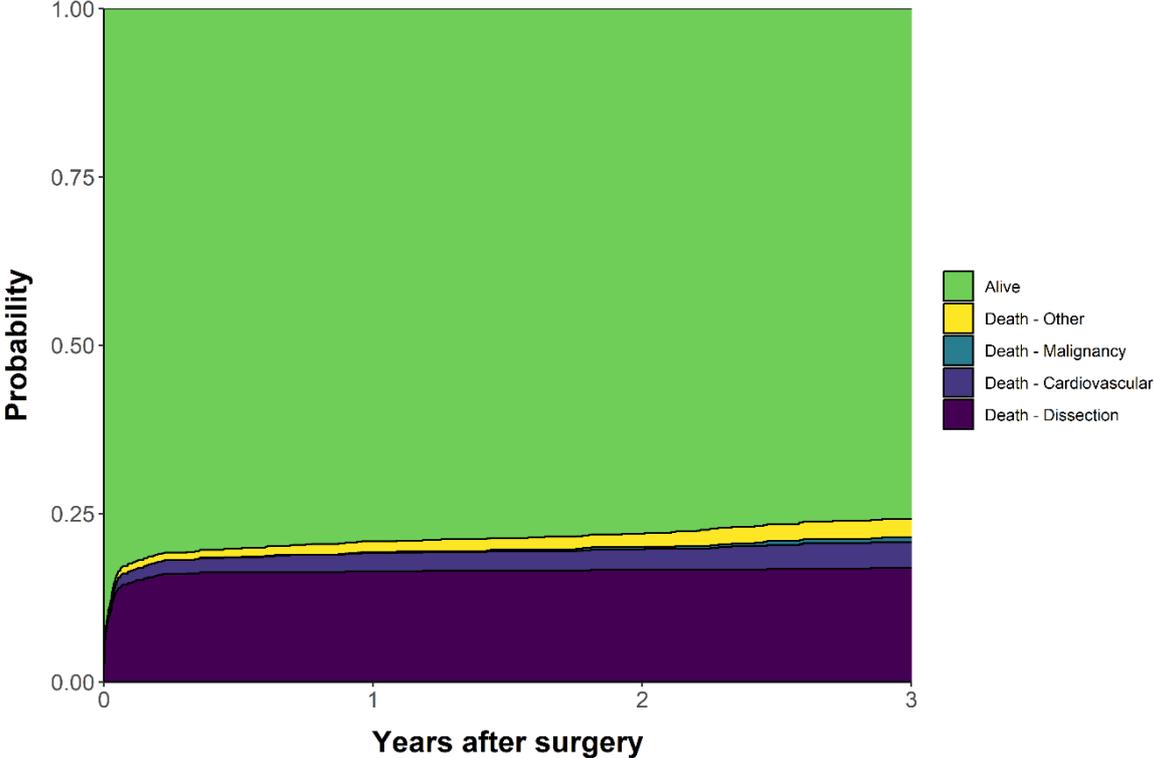

Results

The study population consisted of 1317 patients, of whom 318 died during a median follow-up of 2.3 years. The average age was 63 years and 59% was male. The extent of surgery included the aortic root in 34% and the arch in 73%. In-hospital mortality decreased from 20.4% in 2018 to 13.9% in 2021. Compared to 2018, the adjusted mortality odds ratios were 0.87 (95%CI 0.58-1.30), 0.78 (95%CI 0.52-1.18), and 0.63 (95%CI 0.41-0.95) for 2019, 2020, and 2021, respectively. In the majority (n=222, 70%), the cause of death was related to their aortic dissection (*Figure 1*). However, 365-day survivors only died from (consequences of) their aortic dissection in 14% (6/43 deaths after 1-year), and died from other cardiovascular causes in 37% and cancer in 16%.

Conclusions

In-hospital mortality after surgery for type-A dissection in The Netherlands has decreased over recent years. Patients who survive one year after surgery, seldomly die from the consequences of their dissection, but die from other cardiovascular diseases and cancer.

Figure 1. Causes of death after surgery for type-A aortic dissection in the Netherlands.

Objectives

Post-cardiotomy cardiogenic shock (PCCS), which is defined as severe low cardiac output syndrome after cardiac surgery, has a mortality rate of up to 90%. No study has yet been performed to compare patients with PCCS treated by conservative means to patients receiving additional mechanical circulatory support with veno-arterial extracorporeal membrane oxygenation (ECMO).

Methods

A single-center retrospective analysis from January 2018 to June 2022 was performed.

Results

Out of 7.028 patients who underwent cardiac surgery during this time period, 220 patients (3%, $p < 0.001$) developed PCCS. The patients were stratified according to their severity of shock based on the Stage Classification Expert Consensus (SCAI) group. Known risk factors for shock-related mortality, including the vasoactive-inotropic score (VIS) and plasma lactate levels, were assessed at structured intervals. In patients treated additionally with ECMO ($n=73$, $p < 0.001$), the in-hospital mortality rate was 60%, compared to an in-hospital mortality rate of 85% in patients treated by conservative means (non-ECMO; $n=52$, $p=0.003$). In 18/73 (25%) ECMO patients, the plasma lactate level normalized within 48 hours, compared to 2/52 (4%) in non-ECMO patients ($p=0.002$). The morbidity of non-ECMO patients compared to ECMO patients included a need for dialysis (42% vs. 60%, $p=0.047$), myocardial infarction (19% vs. 27%, $p=0.292$), and cerebrovascular accident (17% vs. 12%, $p=0.435$).

Conclusion

In conclusion, the additional use of ECMO in PCCS holds promise for enhancing outcomes in these critically ill patients, more rapid improvement of end-organ perfusion, and the normalization of plasma lactate levels.

LONG-TERM OUTCOMES IN HYBRID VERSUS STANDALONE THORACOSCOPIC ABLATION IN PATIENTS WITH ATRIAL FIBRILLATION: A SYSTEMIC REVIEW AND RECONSTRUCTED INDIVIDUAL PATIENT DATA META-ANALYSIS.

Luca Aerts^{1,2}, Michal J. Kawczynski^{1,2}, Justin G.L.M. Luermans^{2,3}, Jos G. Maessen^{1,2}, Elham Bidar^{1,2}, Samuel Heuts^{1,2}, Bart Maesen^{1,2}

¹Department of Cardiothoracic Surgery, Maastricht University Medical Centre, Maastricht, The Netherlands; ²Cardiovascular Research Institute Maastricht (CARIM), Maastricht University, Maastricht, The Netherlands; ³Department of Cardiology, Maastricht University Medical Centre, Maastricht, The Netherlands

Objectives

Thoracoscopic hybrid and standalone thoracoscopic atrial fibrillation (AF) ablation have demonstrated favorable outcomes in the management of AF patients. Currently, it's unknown whether there is a difference in long-term freedom from AF when comparing these two procedures.

Methods

A systematic search (2012 – 2023) was performed using: 'thoracoscopic ablation,' 'hybrid ablation,' 'atrial fibrillation,' and various alternative spellings. Articles presenting Kaplan-Meier (KM) curves were included for pooled analysis of freedom from atrial tachyarrhythmia (ATA). Individual time-to-event data were reconstructed from the KM curves and included in a multivariable Cox and frailty Cox model with adjustments for age, sex, type of AF and AF duration.

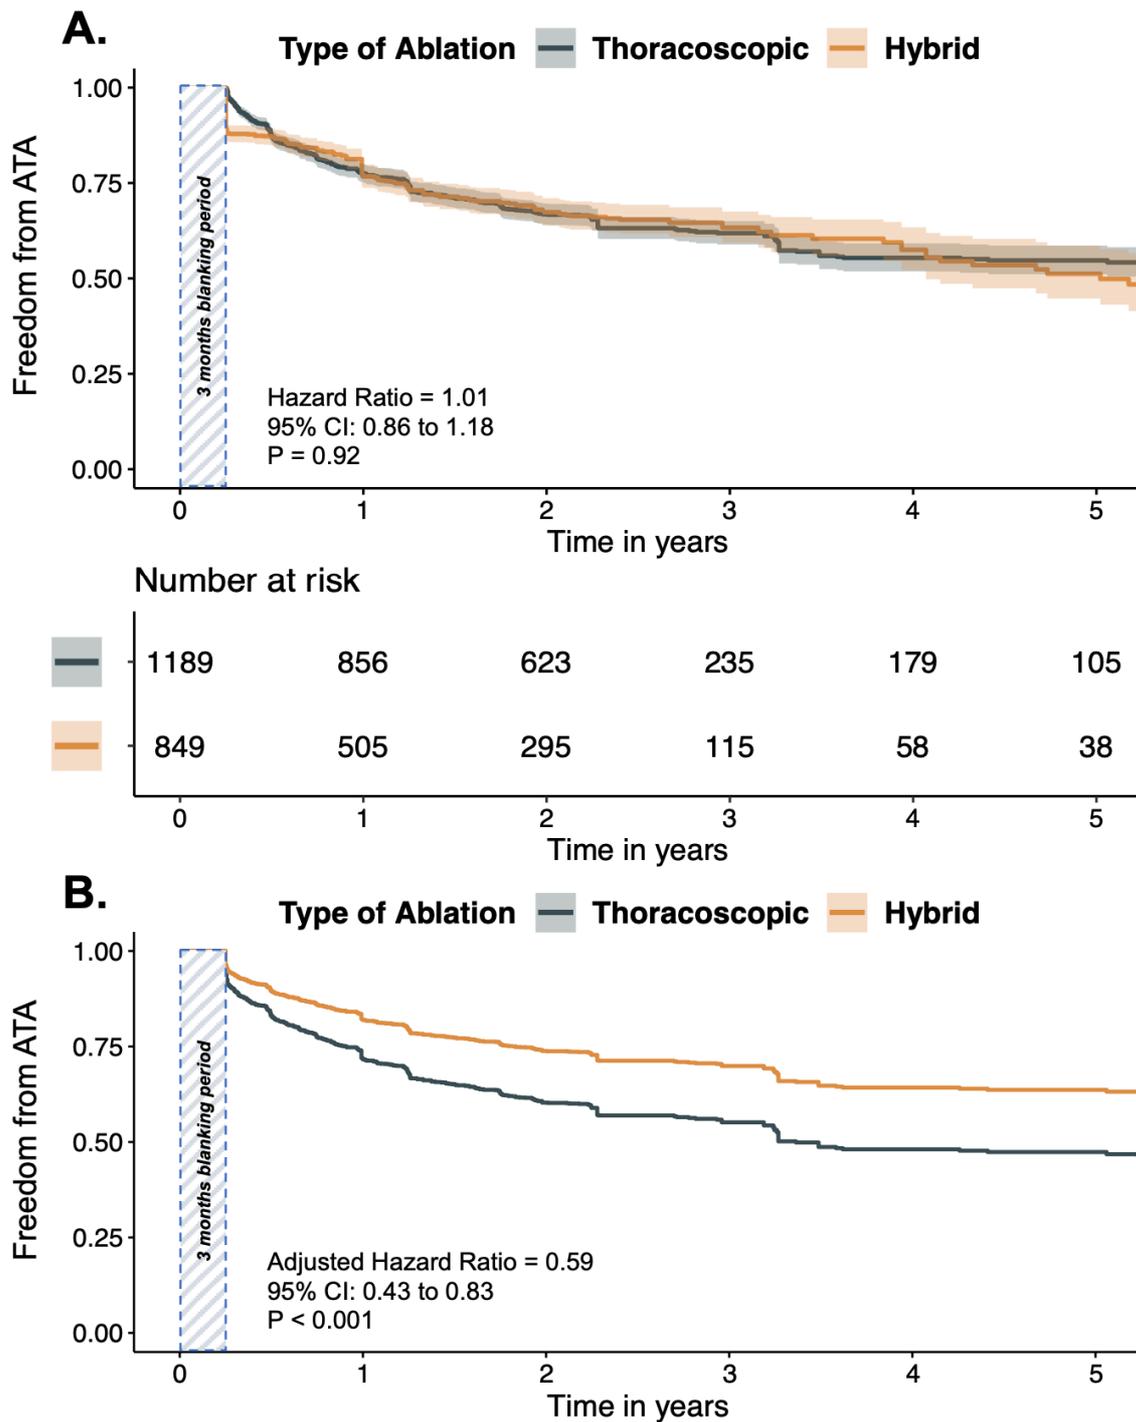

Results

18 studies were included in the meta-analysis for long-term freedom from ATA, comprising 2215 patients. Patients undergoing hybrid ablation were older (62.0 vs. 58.8 years old, $p=0.046$), had less frequently paroxysmal AF-history (9.6% vs. 32.1%, $p<0.01$), and had a longer duration of AF-history (7.0 vs. 5.3 years, $p=0.04$), compared to patients undergoing standalone thoracoscopic ablation. There were no significant differences in complications between the two ablation procedures. Adjusted analysis revealed that hybrid ablation was significantly associated with greater freedom from ATA (Hazard Ratio [HR]=0.59, 95%CI: 0.43-0.83, $p<0.001$) compared to standalone thoracoscopic ablation (Figure 1A). Adjusted freedom from ATA at 1 year, 3 years, and 5 years was 71.6%, 55.1%, and 46.8% for thoracoscopic, and 82.0%, 69.9%, and 63.6% for hybrid ablation (Figure 1B).

Conclusion

Hybrid thoracoscopic AF-ablation is associated with a higher level of freedom from ATA when compared to standalone thoracoscopic ablation.

Figure 1. Unadjusted and adjusted KM-curves for freedom from ATA for thoracoscopic and hybrid AF-ablation.

STAGED HYBRID APPROACH FOR TYPE A ACUTE AORTIC DISSECTION : ZONE 2 ARCH REPLACEMENT AND COMPLETION TEVAR UPON INDICATION

Nabil Saouti,¹ Guillaume S.C. Geuzebroek,¹ Koko Li*,¹ Foeke J.H. Nauta,¹ Wilson Li,¹ Michel Verkroost,¹ Robin H. Heijmen¹

¹ Radboud UMC, Nijmegen, * Presenter

Objectives

Downstream aortic dilatation following hemiarch repair for acute type A aortic dissection (TAAD) requires complex redo surgery of the arch. To prevent this we have adopted an approach where at the index operation the distal suture line is in zone 2 and at the same time by proximalisation of the first two arch arteries creating a landing zone for a (completion) TEVAR upon indication (i.e. postdissection dilatation).

Methods

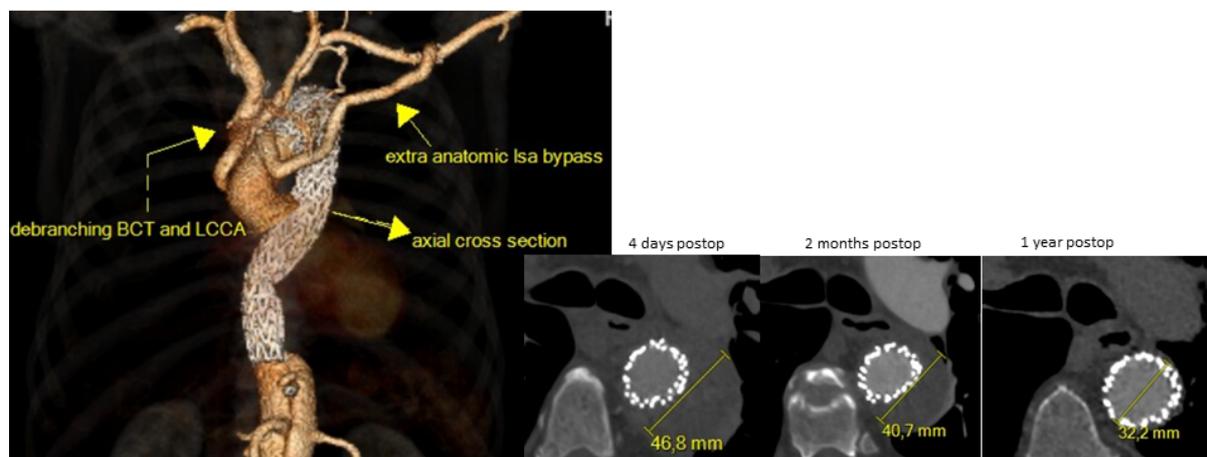

We retrospectively analyzed all patients at our center that underwent this new approach during 2022 and 2023.

Results

We identified 25 patients (out off a total of 91) that were treated by Zone 2 arch repair for TAAD. No mortality was observed. One patient had a stroke and one patient had a minor stroke which completely recovered. All patients were discharged home. At follow-up, CTA-scanning was performed to check for early dilatation at the downstream aorta. If so, completion TEVAR was performed, together with LSA-bypass grafting, the TEVAR extending from the mid-arch upto the celiac trunk to exclude false lumen flow along the entire thoracic aorta. A total of 8 patients had completion TEVAR without any neurological events. Favorable remodeling was seen in all 7 patients who had their CTA-scanning during follow-up (Figure).

Conclusion

Staged hybrid approach with zone 2 arch replacement followed by completion TEVAR upon indication may be considered a safe and promising approach in acute type A aortic dissection (Debaakey type 1), to exclude the false lumen in the downstream thoracic aorta inducing favorable remodeling and preventing postdissection aneurysm formation.

Objectives

While it is known that stent-graft deployment and acute arch angulation increase aortic stiffness, the impact of surgical interposition grafting remains unclear. We investigated the impact of open surgery on aortic stiffness and compared this with stent-graft induced aortic stiffening, utilising an *ex vivo* model.

Methods

Porcine thoracic aortas were connected to a mock circulatory loop. Baseline characteristics, proximal and distal flow curves (for PWV calculation), and blood pressures were recorded in a type I and III arch configuration. Subsequently, 10cm proximal descending aorta was excised and replaced with Dacron® (IGK0018-40S | Fig.1). After surgery, all measurements were repeated in both arch configurations. Available experimental literature data on stent-graft induced aortic stiffening was used for comparison.

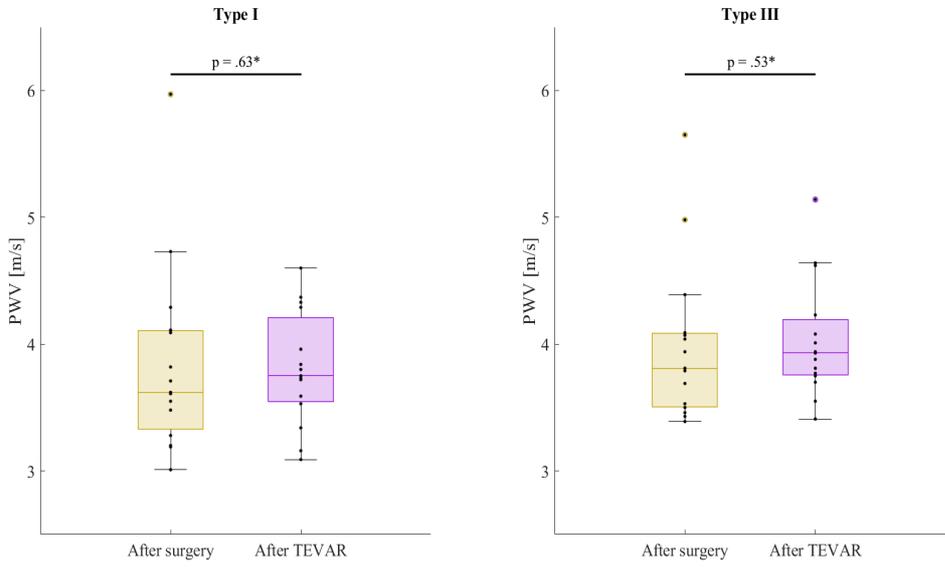

Results

Fifteen aortas were prepared and attached to the circuit. After surgery, with both arch configurations, mean aortic PWV increased (Type I: 3.46 to 3.84m/s (+10.7%), $p < .001$); Type III: 3.61 to 3.98m/s (+10.4%), $p = .001$), systolic pressure remained stable, diastolic pressures decreased (Type I: 73 to 65mmHg, $p < .001$; Type III: 75 to 66mmHg, $p < .001$), and consequently mean arterial pressure decreased (Type I: 89 to 85mmHg, $p = .020$; Type III: 92 to 85mmHg, $p = .001$). Compared with stent-graft induced aortic stiffening and with both arch configurations, baseline aortic PWV was similar, and there was no difference in aortic PWV after open or endovascular repair (Type I open vs stent-graft: 3.84 vs 3.81m/s, $p = .63$; Type III open vs stent-graft: 3.98 vs 4.03m/s, $p = .53$ | Fig.1).

Conclusion

Surgical interposition grafting of the proximal descending aorta increases aortic PWV and decreases diastolic blood pressure. This aortic stiffening is comparable to stent-graft induced stiffening.

⁷*Department of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, the Netherlands.*

Objectives

Right ventricular (RV) failure following pulmonary regurgitation (PR) is frequently seen late after correction of tetralogy of Fallot. Clinical markers fail to predict which patients are at risk and require interventions. In this study, ventriculo-arterial coupling (VAC) was investigated as an early marker of RV dysfunction by serial assessments in a model mimicking tetralogy of Fallot.

Methods

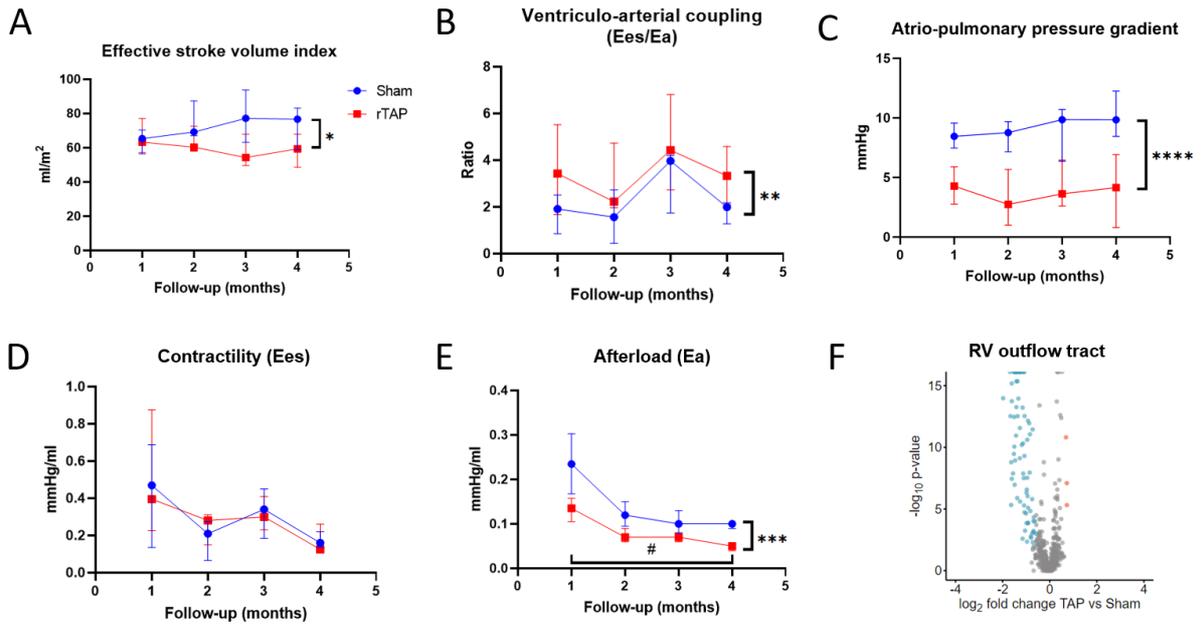

In neonatal pigs, pulmonary artery banding induced RV hypertrophy during 1 month. Subsequently, banding was removed and PR was created by a transannular patch repair (rTAP, n=10). Sham animals (n=6) underwent sham surgeries. Over 4 months of follow-up, monthly pressure-volume loops were performed to assess contractility, afterload and their ratio VAC. Proteomics was performed on RV outflow tract and free wall myocardium.

Results

Despite decreased effective stroke volume index, VAC was preserved over time in PR. Although contractility was similar to sham, PR lowered afterload drastically and end-diastolic pulmonary artery pressures almost approximated right atrial pressure. Proteomics analysis showed changes in metabolic pathways, mainly in the outflow tract of rTAP animals.

Conclusions

VAC is preserved and not suitable as an early marker of RV dysfunction. The decrease in afterload, likely the consequence of diastolic emptying of the pulmonary artery into the RV, may pseudo-normalize systolic function. While contractility was similar to Sham, proteomics reveal an increased metabolic burden on the RV myocardium of rTAP animals, with the outflow tract being more affected than the free wall.

(A-E) Hemodynamics over time, presented as median [IQR]. (F) Differential protein expression in the RV outflow tract.

³*Cardiovascular Research Institute Maastricht (CARIM), Maastricht, The Netherlands*

⁴*Department of Cardiothoracic surgery, Medisch Spectrum Twente, Enschede, The Netherlands.*

Objectives

Postoperative atrial fibrillation (POAF) frequently occurs after cardiac surgery, often with recurring episodes post-discharge (late-POAF). While clinical factors such as age and increased atrial volumes are associated with late-POAF recurrence, it is unknown if atrial histological characteristics are also linked to late-POAF. Therefore, this study aimed to investigate these associations with long-term continuous rhythm monitoring after cardiac surgery.

Methods

Consecutive patients with and without AF-history were prospectively included. Intraoperatively, biopsies were taken of left (LAA) and right atrial appendages (RAA), and all patients received an implantable loop recorder for a period of 2.5 years. Late-POAF was defined as an AF-episode lasting at least 2 minutes after the first 30 days post-surgery. Late-POAF burden was calculated as the percentage of time in AF till follow-up ending.

Results

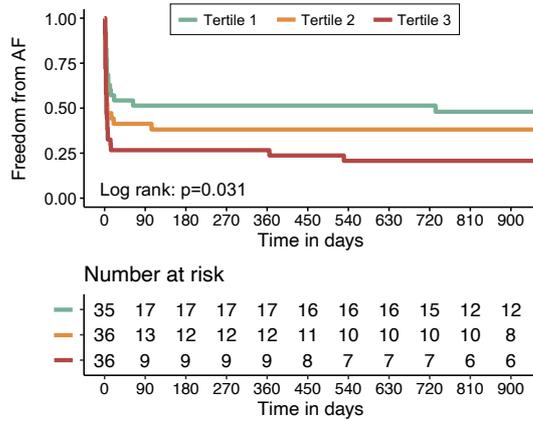

A total of 133 patients were included (90 without and 43 with AF-history). Any-POAF occurred in 81 patients (60.9%) and late-POAF in 53 patients (40.8%). Increased RAA endomysial fibrosis was significantly associated with any-POAF and late-POAF in the unadjusted analysis (Figure 1A-B), but no longer after adjustments for age, sex, and AF-history. Increased RAA endomysial was the only histological trait significantly associated with increased overall and late-POAF burden after adjusting for confounders (Figure 1C-D).

Conclusion

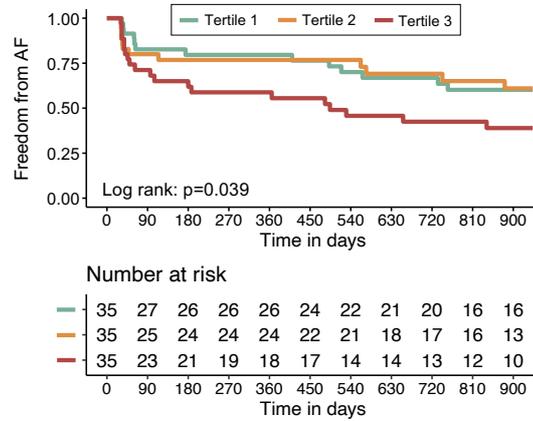

Increased RAA endomysial fibrosis is significantly associated with a higher late-POAF burden independently of relevant confounders. These findings suggest that while the role of RAA endomysial fibrosis in late-POAF incidence (trigger-based) may be less prominent, it is crucial in predicting late-POAF burden (substrate-based AF perpetuation).

ARTIFICIAL INTELLIGENCE-BASED PULMONARY VESSEL SEGMENTATION: AN OPPORTUNITY FOR AUTOMATED 3D-PLANNING OF LUNG SEGMENTECTOMY

Quinten J. Mank¹, Abdullah Thabit², Alexander P.W.M. Maat¹, Sabrina Siregar¹, Theo van Walsum², Jolanda Kluin¹, Amir H. Sadeghi^{1,3}

¹Department of Cardiothoracic surgery, Thoraxcenter, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands; ²Biomedical Imaging Group Rotterdam, Departments of Radiology Medical Informatics, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands; ³Department of Cardiothoracic surgery, University Medical Center Utrecht, Utrecht, The Netherlands

Objectives

This study aims to evaluate an Artificial Intelligence (AI) based approach for automated segmentation of pulmonary arteries and veins in both the left and right lung from Computed Tomography (CT) images. The goal is to provide a supporting tool for surgeons in preoperative planning of lung segmentectomies by enhancing their anatomical knowledge and 3D visualization of the patient-specific anatomy.

Methods

A dataset of 126 CT scans of patients undergoing lung segmentectomy at the Erasmus MC was collected between March 2021 and December 2023. A Deep Learning (DL)-model was trained to learn segmentation maps based on manually annotated CT-scans. The DL-models were assessed using the following evaluation metrics: Dice score, Jaccard Index, and Sensitivity. Additionally, an evaluation of the clinical usability was performed using intraoperative recordings of 6 robotic-assisted segmentectomy procedures and DL-model outputs.

Results

The DL-models achieved average evaluation scores of 0.915 (Dice), 0.845 (Jaccard), and 0.85 (Sensitivity). The DL-based automatic approach demonstrated a reduction in segmentation processing time (~1.5h for manual vs. <5 min for automatic segmentation).

Conclusion

In summary, we have developed and assessed an AI-based pulmonary vessel segmentation tool, achieving a high technical accuracy (average DICE 0.915). It shows promise for lung segmentectomy planning based on a limited clinical usability analysis. Despite certain challenges such as ensuring robustness across diverse patient populations and generalizability to anatomical variations and pathological conditions within the lung, this DL approach demonstrates potential as a potent tool for pulmonary vessel segmentation. It offers promise to change the precise segmentectomy planning.

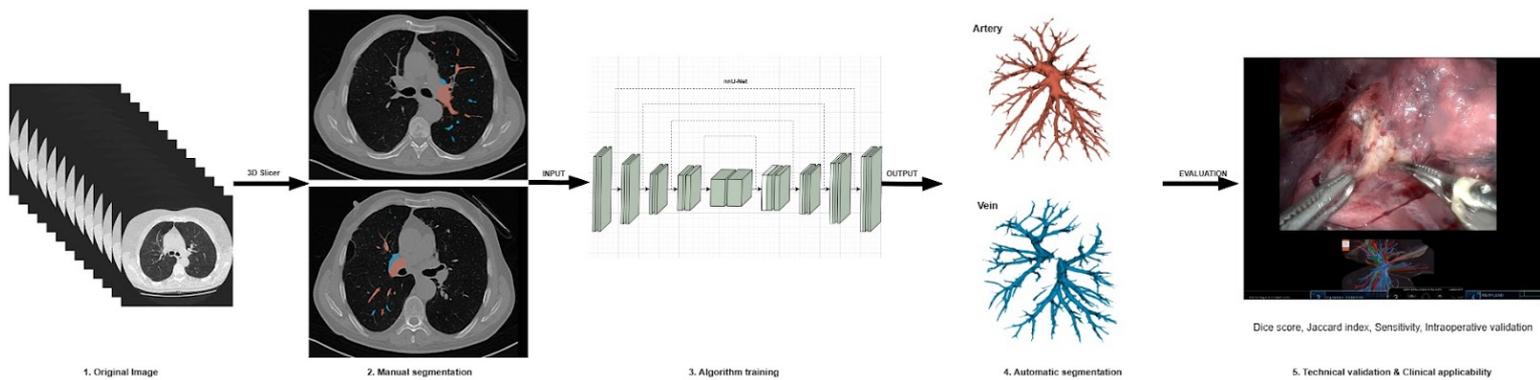

Fig 1. Workflow diagram of the DL-based pulmonary vessel segmentation.
